ChatGPT development process

LP Guard Live Position Planner | September 2026

Purpose. This document contains selected, project-relevant excerpts from my work with ChatGPT. It is intentionally not a full transcript. The excerpts show how I used the assistant to define the original LP Guard concept, narrow it into a JavaScript 102 project, review generated work, identify problems, and test revisions.

1. Defining the larger LP Guard architecture

September 21, 2026

> *User prompt excerpt: "I want you to create a very detailed write up of what this build intends to accomplish ... explicitly focus on our plan ... detailing what Guard, Ledger, Risk and Optimize should be to this application and ... each specific state in the machine and its function."*

Assistant response / outcome: ChatGPT helped organize the larger application into distinct responsibilities and state-machine roles rather than treating LP Guard as one undifferentiated program.

What this demonstrates: I was using the assistant to document and reason about a real project I had already been developing, including architecture and state responsibilities.

2. Questioning an authorization rule

September 21, 2026

> *User prompt excerpt: "receiving an asset does not authorize use, assignment does. elaborate please."*

Assistant response / outcome: The discussion separated possession/receipt of an asset from authority to use it, which became part of the larger project's Guard boundary and policy model.

What this demonstrates: I challenged a design statement and asked for the reasoning behind it instead of simply accepting generated text.

3. Catching an API interpretation problem

October 1, 2026

> *User prompt excerpt: "everything looks fantastic visually but here's something that doesn't look optimal."*

Assistant response / outcome: The screenshots revealed that one returned pair was oriented as USDT/WETH, causing the displayed "ETH price" to be near $1. ChatGPT revised the pair normalization and market-selection logic.

What this demonstrates: I did not treat a polished interface as proof that the data logic was correct; I checked the output and reported a mismatch.

4. Retesting after a UX/API revision

October 1, 2026

> *User prompt excerpt: "The selection changed screen is a phenomenal addition although there are still no matching market found messages. With the addition of the selection changed screen I am sure that I clicked load live data each time."*

Assistant response / outcome: The project was simplified to a consistent WETH/USDC comparison and the market lookup was revised again until Base, Arbitrum, and Ethereum all returned live data.

What this demonstrates: I retested after a revision, distinguished a UX improvement from the remaining data problem, and supplied evidence that the failure was reproducible.

5. Finding a broken planner interaction

October 1, 2026

> *User prompt excerpt: "I'm clicking Analyze position and nothing is happening."*

Assistant response / outcome: ChatGPT traced the failure to a stale JavaScript reference left from the removed stablecoin selector. The reference was replaced and the planner was retested.

What this demonstrates: I manually exercised the generated feature and reported a functional failure rather than assuming the code worked because the page rendered.

6. Final functional validation

October 1, 2026

> *User prompt excerpt: "Okay I did in range, above range, below range, invalid range. all work as intended."*

Assistant response / outcome: The four key planner states were confirmed after the fix. I then separately tested Reset, Feedback, and responsive resizing.

What this demonstrates: The final product was validated through specific behavioral cases, not only visual inspection.

Summary of AI Use

ChatGPT functioned as a coding and reasoning partner across two layers of the work: the larger Python LP Guard project and the simplified JavaScript 102 website. I supplied the domain goals, architecture questions, test observations, and corrections. The assistant helped translate those goals into code, explain concepts, isolate bugs, and revise the implementation. The submitted website was reviewed and tested through multiple iterations rather than being accepted from the first generated version.
